# INITIALE<sup>®</sup> STRAIGHT CEMENTED FEMORAL STEM

## Design:

INITIALE<sup>®</sup> straight femoral stems are intended for use with cement. Neck-shaft angle evolves with size. Intramedullary shape is defined by a progressive decrease of the curve in the frontal plane.

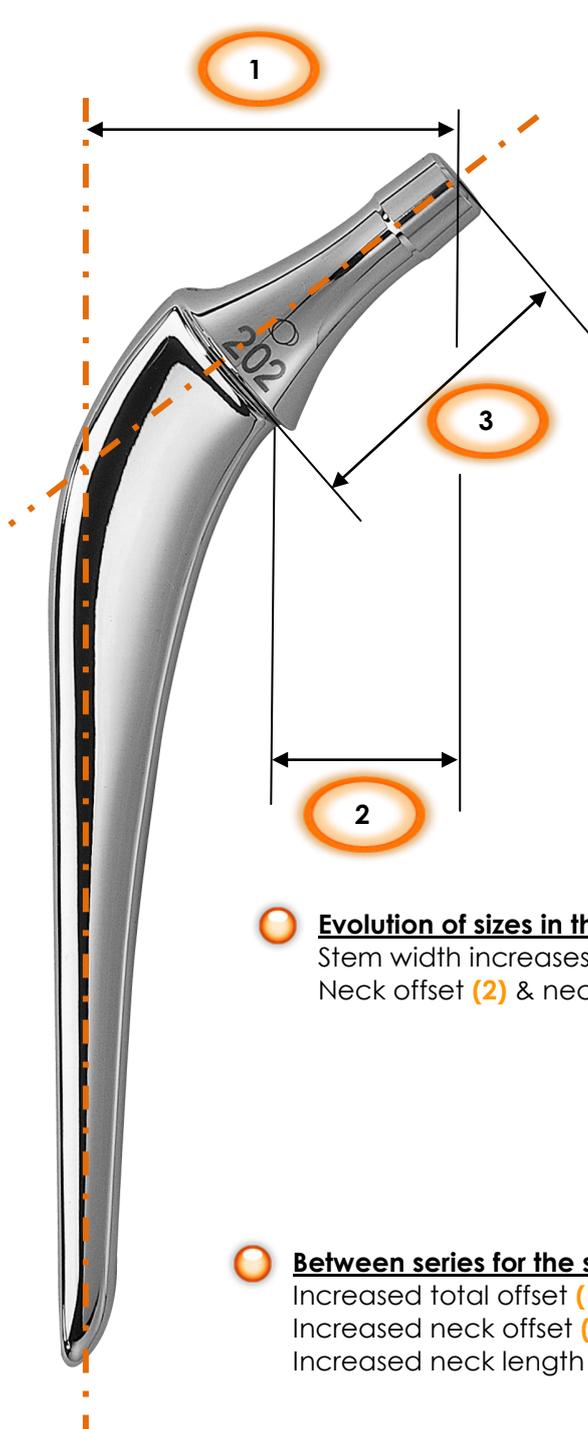

**Cross-section of the stem is quadrangular.**

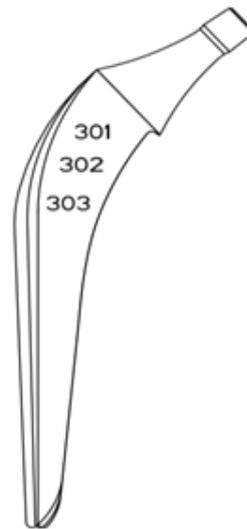

**Material:** M30NW Stainless Steel

# INITIALE<sup>®</sup> STRAIGHT CEMENTED FEMORAL STEM

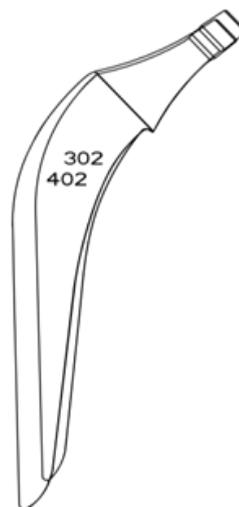

## Evolution:

- 1 Total Offset
- 2 Neck Offset
- 3 Neck length

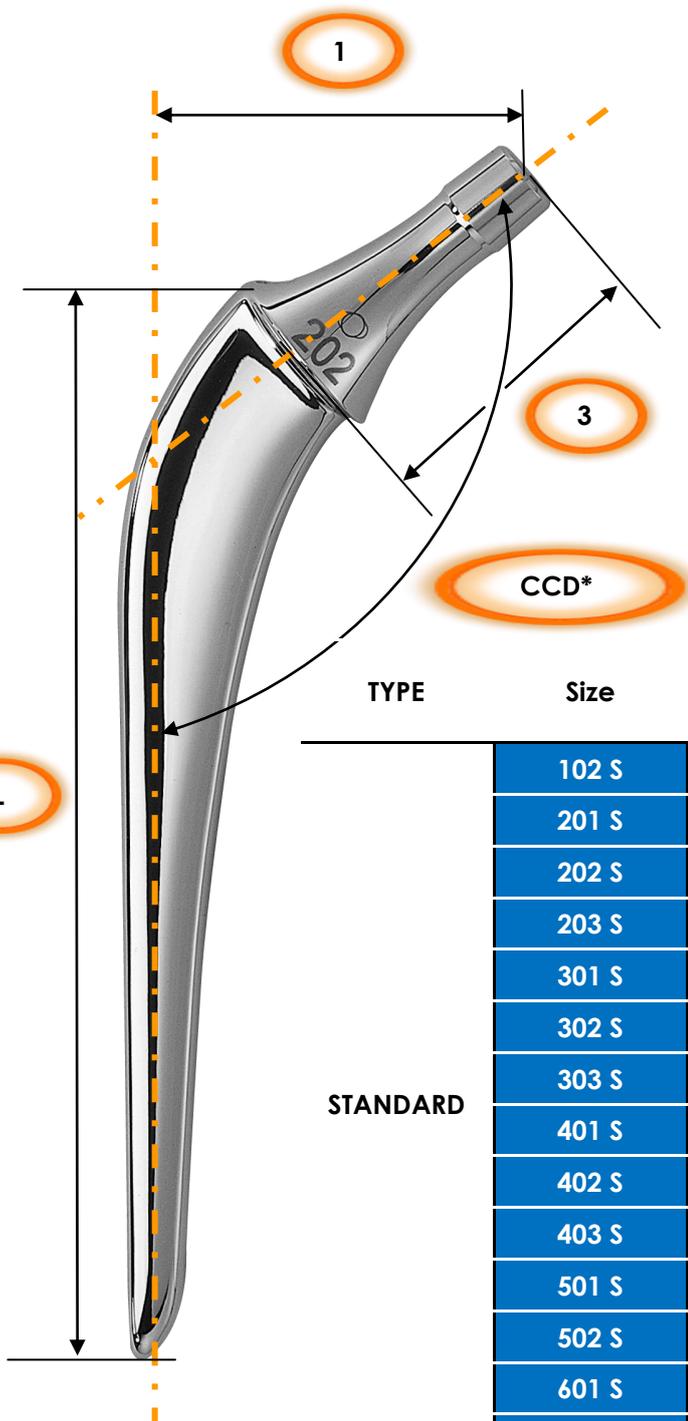

- **Evolution of sizes in the same series:**  
Stem width increases => intra-medullary congruency (1).  
Neck offset (2) & neck length (3) stay the same.

- **Between series for the same size:**  
Increased total offset (1).  
Increased neck offset (2).  
Increased neck length (3).

# INITIALE<sup>®</sup> STRAIGHT CEMENTED FEMORAL STEM

## Evolution:

**302S** →

- S => Standard
- D => Dysplasia
- R => Revision

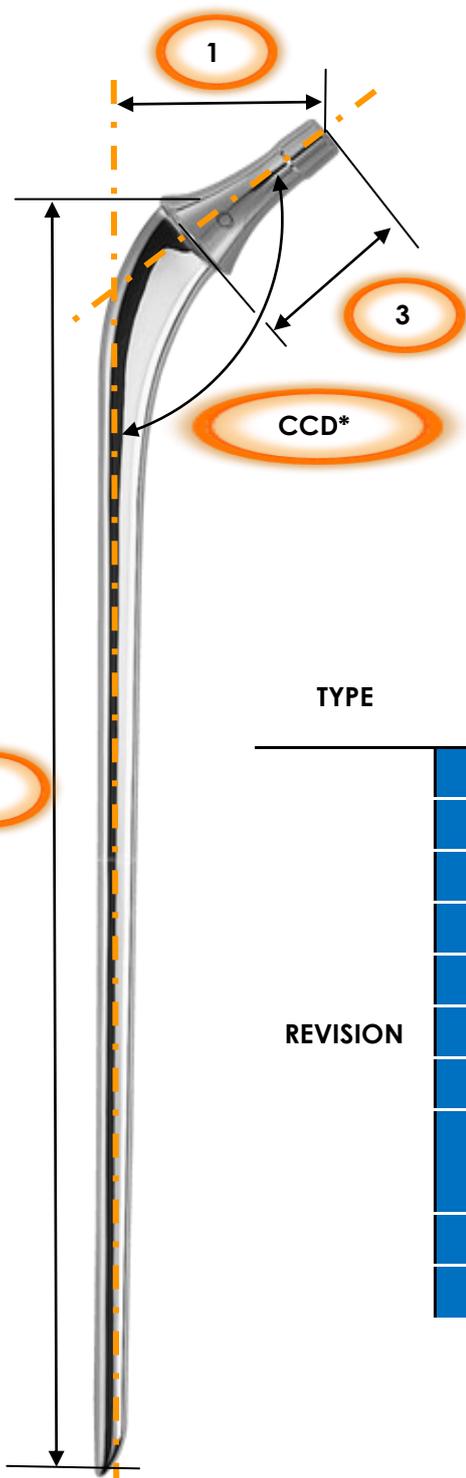

**300** => identifies the series

**2** => Stem size number in the series

## PREOPERATIVE PLANNING

Pre-op planning is an important step to determine the implant size most adapted to restore the patient's anatomy. It must take into account anatomical and quality factors (bone quality, bone density, patient's morphology).

INITIALE<sup>®</sup> femoral stem features several offset options and different angles (see pages 6 & 7), and the range is comprised of standard, dysplasia and revision versions.

- It is advised to choose an implant size allowing optimal fill of the femoral canal, leaving an even cement mantle around the stem.
- Stem choice and neck resection level must bring the best leg length and offset restoration possible. Neck resection level must be assessed closely.

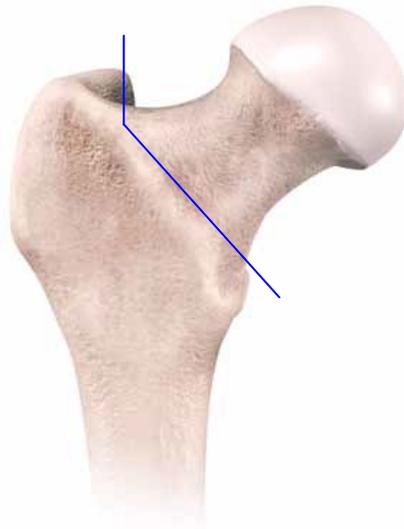

### REMINDER

This surgical technique is intended for proper use of the instrumentation set. The surgical approach and the operating technique are entirely under the surgeon's responsibility.

### NOTE

The x-ray templates are provided at a scale of 1:15, and can be provided with a personalized scale on request.

## FEMORAL NECK RESECTION

Neck resection level, defined by templating, is reproduced based on anatomical landmarks (greater trochanter, lesser trochanter, trochanteric fossa).

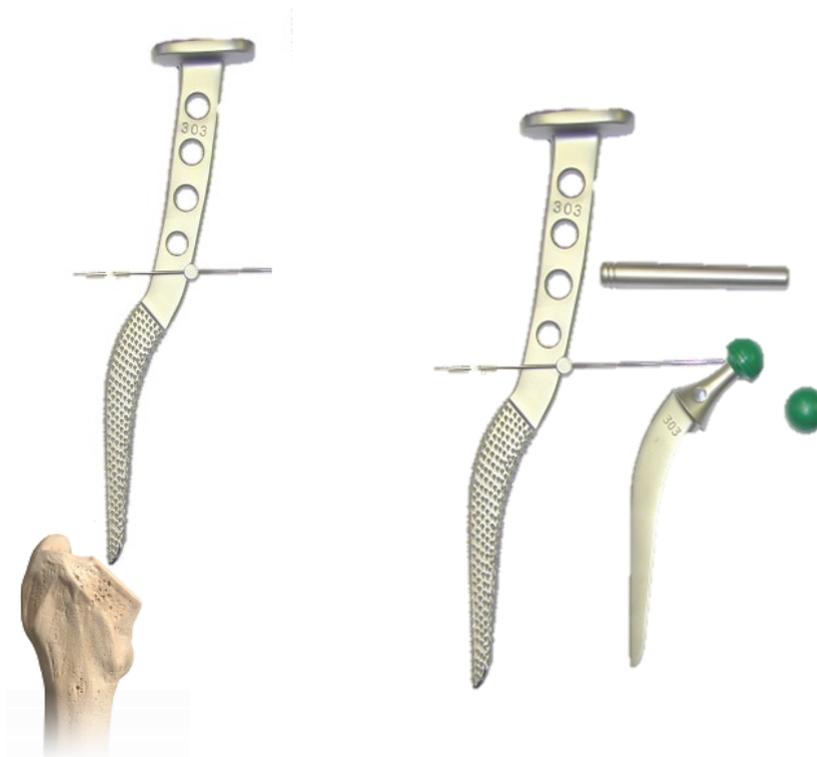

As the stem features a collar, it is necessary to orient the resection in the sagittal plane in order to obtain the desired anteversion.

Medullary canal broaching can be performed before or after acetabular preparation.

Neck resection can be done before or after femoral head dislocation. Start by hollowing the femoral neck from its trabecular bone (some amount can be kept in order to be used as cement distal plug if necessary). Make sure to carefully prepare the supero-external part of the neck to avoid any varus positioning of the stem.

# INITIALE<sup>®</sup> STRAIGHT CEMENTED FEMORAL STEM

## BROACHING

### Femoral canal opening:

Femoral canal is prepared with the smallest broach, then with increasing broaches.

### Metaphyseal preparation:

Broach successively until templated size has been reached. Broaches are slightly oversized and feature teeth in order to have enough clearance for bone cement.

To control leg length, insert the blunt K-wire in the broach handle. This represents the horizontal projection of a medium neck femoral head.

### NOTE

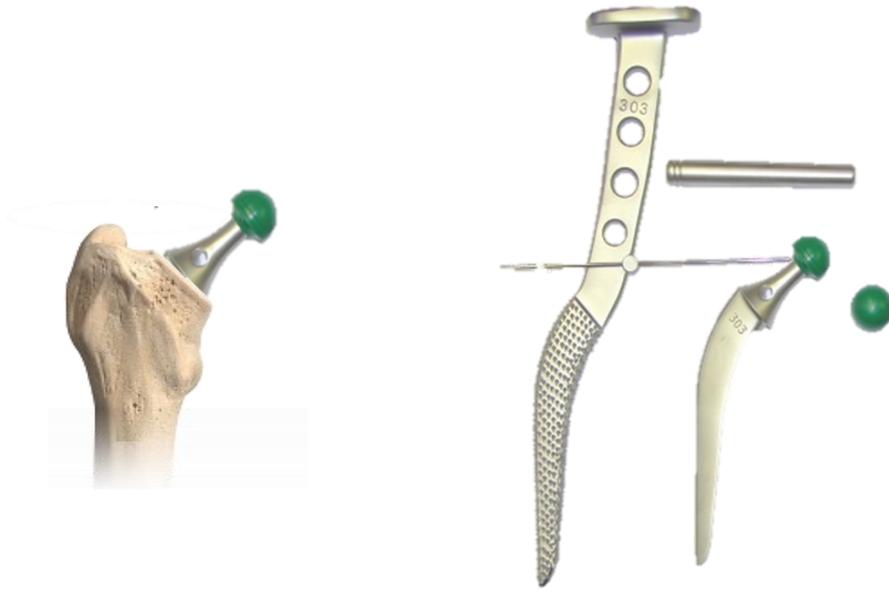

For INITIALE<sup>®</sup> Revision, ream the diaphyseal canal over at least the length of the final stem

### NOTE

INITIALE<sup>®</sup> broaches range offers several broach designs adapted to the surgical approach (Direct anterior, antero-lateral, posterior)

# INITIALE<sup>®</sup> STRAIGHT CEMENTED FEMORAL STEM

## TRIALS ON TRIAL STEM

Choose the trial stem of the same size as the last broach. Place the trial stem in the femur, with a trial head of the desired size and length.

Extra-long neck

Reduce the joint using the femoral head impaction, assembled on the universal handle. Test range of motion and joint stability (no impingement) in order to validate extra-medullary settings.

Check rotational stability of the trial stem, collar matching with neck resection, and anteversion with the broach handle extraction shaft.

### NOTE

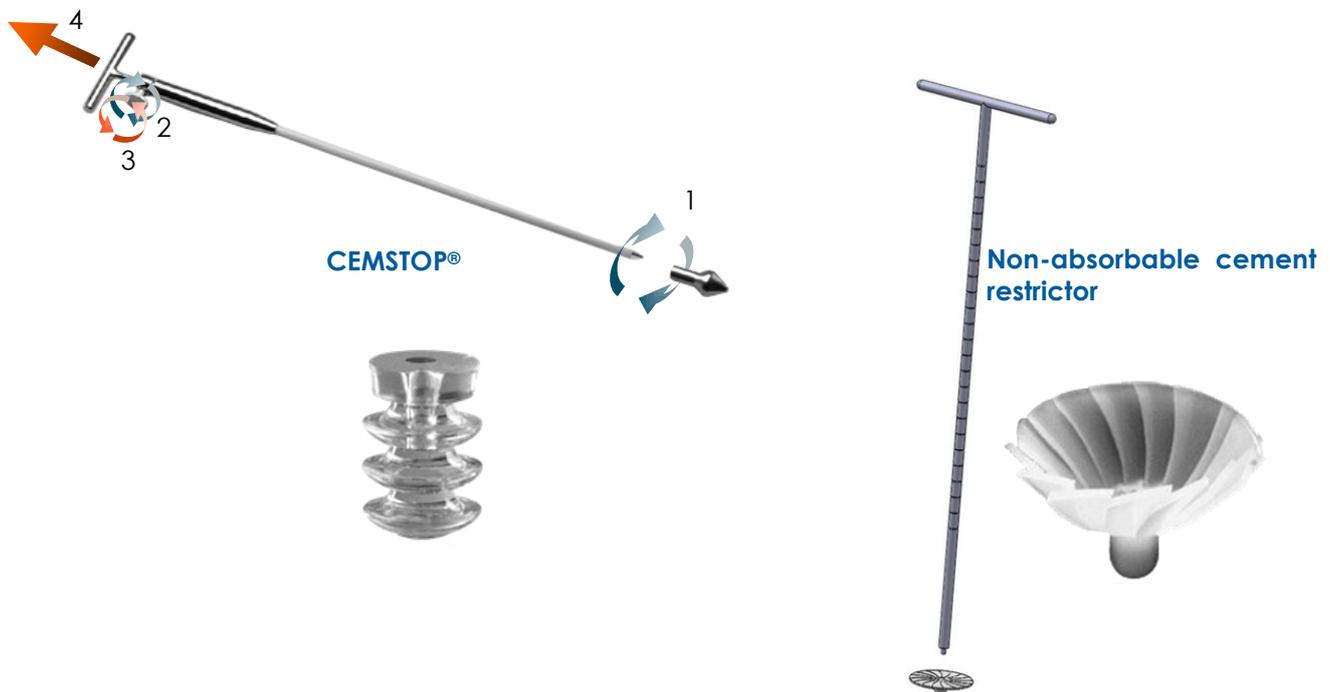

Perform trials until reaching anteversion and neck length that offers the best stability and range of motion.

### NOTE

Blunt K-wire placed in the broach handle allows visual assessment of the medium neck head center to reproduce templating.

# INITIALE<sup>®</sup> STRAIGHT CEMENTED FEMORAL STEM

## CEMENT RESTRICTOR INSERTION

Wash and dry the intramedullar femoral cavity. Femoral canal obturation should be performed according to the surgeon's habits. The AMPLITUDE range offers the CEMSTOP<sup>®</sup> absorbable restrictor and a non-absorbable UHMWPE restrictor.

Introduce the cement restrictor according to following instructions depending on the model used:

### CEMSTOP<sup>®</sup> :

- Based on femoral canal preparation, determine in the instrumentation the adequate trial "olive" diameter and assemble it on the handle by threading it completely (1).
- Tighten the holding screw on the body of the inserter (2).
- Compare the length with the validated broach by using a landmark that can be used to determine adequate insertion depth.
- Insert in the femoral canal until determined depth is reached to assess the diameter. Repeat trials until diameter has been validated. Remove the trial "olive" by unthreading it.
- Choose the CEMSTOP<sup>®</sup> restrictor of the same size as the validated trial "olive", assemble it on the inserter, and insert it in the femoral canal.
- Unthread the holding screw (3) and pull the handle to leave the CEMSTOP<sup>®</sup> restrictor in place (4).

### Non-absorbable Cement Restrictor:

- Assemble the non-absorbable restrictor on the introducer.
- The graduation on the inserter indicates insertion depth. Compare with the validated broach by using a landmark that can be used to determine adequate insertion depth. Add 1cm to ensure positioning well below the stem.
- Insert in the femoral canal until determined depth is reached.
- Remove the inserter to leave the restrictor in place

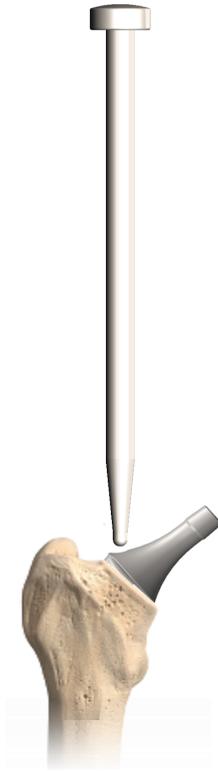

### NOTE

Follow the instruction for use of the cement being used

# INITIALE<sup>®</sup> STRAIGHT CEMENTED FEMORAL STEM

---

## FINAL STEM INSERTION

Following probable muscular or bone reinsertion wires, the medullary canal is washed and dried. Cement is introduced using a bone syringe in the canal. Obturation of the canal is made based on the surgeon's habits.

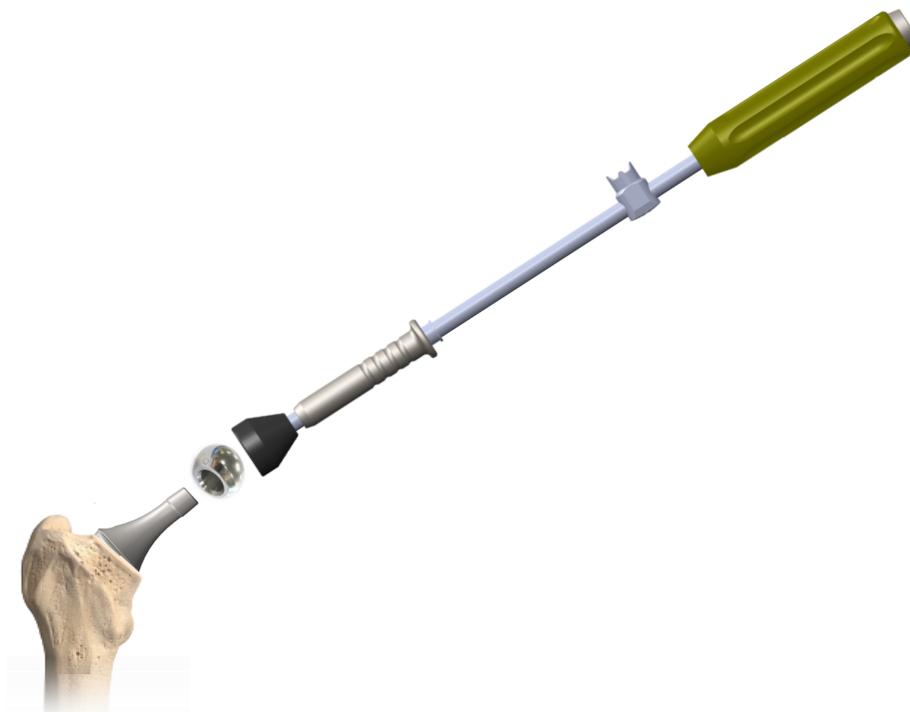

Prosthesis is inserted in the femur and maintained in place until complete cement polymerization thanks to the stem impactor.

It is then possible to perform new trials with trial heads on the stem if necessary (to validate neck length and articular stability).

### NOTE

Follow instructions for use of the cement being used

## FINAL HEAD IMPACTION

Select final femoral head that matches settings validated during trials.

### > Impaction of metallic head:

Make sure the stem taper is clean, dry and undamaged, then position the head manually until it is firmly seated on the taper.

Use the head impactor assembled on the universal handle to impact it axially. Reduce the joint.

### > Impaction of ceramic head:

Before placing the ceramic head onto femoral stem:

- Carefully rinse and dry the stem taper.
- Meticulously inspect the stem taper and female head taper, and remove any foreign body.

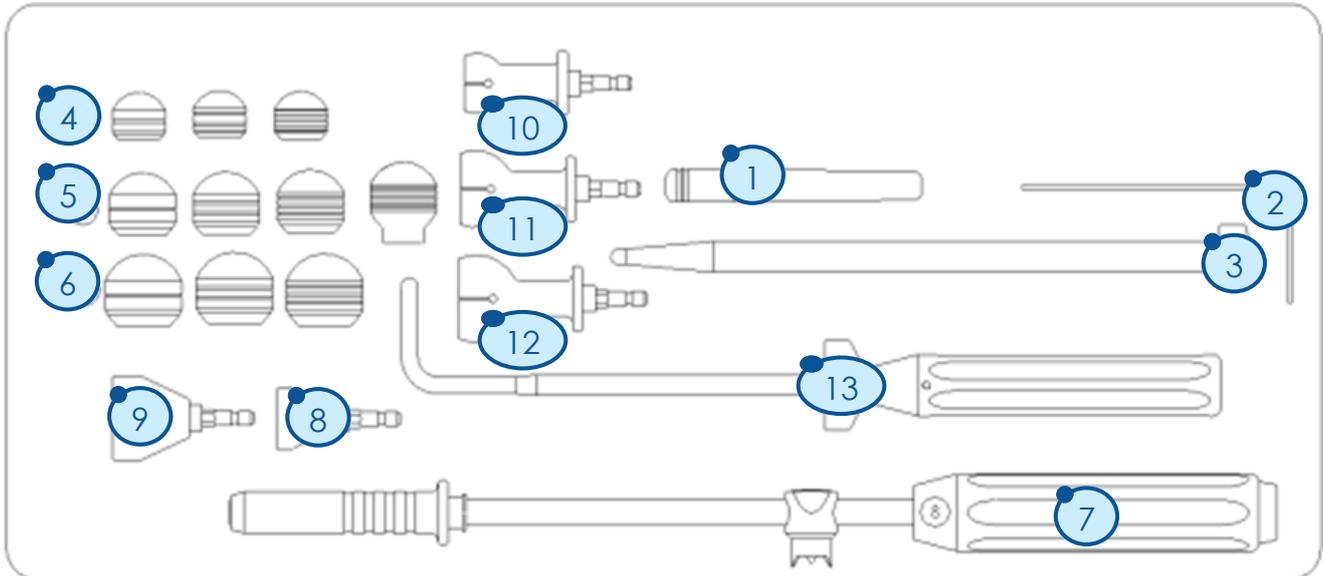

Manually place the head onto stem taper by gently turning it while pushing it along the taper axis until it is firmly seated.

Use the head impactor assembled on the universal handle to impact it axially. Reduce the joint.
